4. Lecture: Introduction to IPCC AR5

Hirokazu Murai
Climate Prediction Division
Japan Meteorological Agency

TCC Training Seminar on Global Warming Projection Information
26 January 2015 (Tokyo, Japan)
This Lecture’s Schedule

14:15 – 16:00

1. About IPCC and its reports
2. What is written in the IPCC AR5
3. Let’s read IPCC AR5
What’s IPCC

Intergovernmental Panel on Climate Change

Establishment: 1988

Purpose:
To provide Scientific view in…

• Climate change
• Environmental and socio-economic impacts
History of IPCC

• First Assessment Report (FAR, 1990)
• Second Assessment Report (SAR, 1995)
• Third Assessment Report (TAR, 2001)
• Fourth Assessment Report (AR4, 2007)
• Fifth Assessment Report (AR5, 2013-2014)
Working Group of IPCC

http://www.ipcc.ch/organization/organization_structure.shtml
Working Group I Report (the first part of AR5)

The Summary for Policymakers (SPM) of the IPCC WGI AR5 was approved at the Twelfth Session of IPCC Working Group I meeting in Stockholm, Sweden, 23 to 26 September 2013 and was released on 27 September.

SPM of Working Group II Report (on 31 March 2014)
SPM of Working Group III Report (on 13 April 2014)
SPM of Synthesis Report (on 2 November 2014)
I recommend you to read the SPM at least once!
This report is using a consistent expression of likelihood and confidence.

Qualitative level: Very high, High, Medium, Low, Very low

SPM of WGI AR5
This Lecture’s Schedule

14:15 – 16:00

1. About IPCC and its reports
2. What is written in the IPCC AR5?
3. Let’s read IPCC AR5
Observed Climate Change (1)

- Warming of the climate system is unequivocal.
- Each of the last three decades has been successively warmer at the Earth’s surface than any preceding decade since 1850.
- For the longest period when calculation of regional trends is sufficiently complete (1901 to 2012), almost the entire globe has experienced surface warming.

Top panel: annual mean values.
Bottom panel: decadal mean values including the estimate of uncertainty for one dataset (black). Anomalies are relative to the mean of 1961–1990.
Left panel: Temperature trends determined by linear regression.

WGI AR5 Figure SPM.1
Observed Climate Change (2)

- Confidence in precipitation change averaged over global land areas since 1901 is low prior to 1951 and medium afterwards.
- Averaged over the mid-latitude land areas of the Northern Hemisphere, precipitation has increased since 1901 (medium confidence before and high confidence after 1951).
- For other latitudes area-averaged long-term positive or negative trends have low confidence.
Observed Climate Change (3)

- Northern Hemisphere spring snow cover and Arctic sea ice have continued to decrease in extent (high confidence).
- Over the last two decades, the Greenland and Antarctic ice sheets have been losing mass, glaciers have continued to shrink almost worldwide.
Observed Climate Change (4)

- Over the period 1901 to 2010, global mean sea level rose by 0.19 [0.17 to 0.21] m.
- The rate of sea level rise since the mid-19th century has been larger than the mean rate during the previous two millennia (high confidence).
- Since the early 1970s, glacier mass loss and ocean thermal expansion from warming together explain about 75% of the observed global mean sea level rise.
Drivers of Climate Change (1)

- Natural and anthropogenic substances and processes that alter the Earth’s energy budget are drivers of climate change.
- The strength of drivers is quantified as Radiative Forcing (RF) in units watts per square metre as in previous IPCC assessments.
- RF quantifies the change in energy fluxes caused by changes in these drivers for 2011 relative to 1750, unless otherwise indicated.
- Positive RF leads to surface warming, negative RF leads to surface cooling.
Drivers of Climate Change (2)

- The RF can be reported based on the concentration changes of each substance. Alternatively, the emission-based RF of a compound can be reported, which provides a more direct link to human activities.
- Total radiative forcing is positive, and has led to an uptake of energy by the climate system.
- The largest contribution to total radiative forcing is caused by the increase in the atmospheric concentration of CO2 since 1750.
Drivers of Climate Change (3)

- It is extremely likely that human influence has been the dominant cause of the observed warming since the mid-20th century.
Before explaining future climate change...

**Representative Concentration Pathways (RCPs)**

- RCPs are four scenarios of assumed pathway in order to project climate change in the future.
- RCP8.5 is a scenario which assumes no additional mitigation.
- RCP2.6 is a scenario which assumes keeping the temperature rise from pre-industrial to less than 2 deg C.
Future Climate Change (1)

- Increase of global mean surface temperatures for 2081–2100 relative to 1986–2005 is projected to 0.3-1.7 °C (RCP2.6), 1.1-2.6 °C (RCP4.5), 1.4-3.1 °C (RCP6.0), 2.6-4.8 °C (RCP8.5).
- The Arctic region will warm more rapidly than the global mean, and mean warming over land will be larger than over the ocean (very high confidence).
Future Climate Change (2)

- Changes in the global water cycle in response to the warming over the 21st century will not be uniform.
- The contrast in precipitation between wet and dry regions and between wet and dry seasons will increase, although there may be regional exceptions.
Extreme precipitation events over most of the mid-latitude land masses and over wet tropical regions will very likely become more intense and more frequent by the end of this century, as global mean surface temperature increases.
Future Climate Change (4)

- Global mean sea level will continue to rise during the 21st.
- Under all RCP scenarios, the rate of sea level rise will very likely exceed that observed during 1971 to 2010 due to increased ocean warming and increased loss of mass from glaciers and ice sheets.
- Global mean sea level rise for 2081–2100 relative to 1986–2005 will likely be in the ranges of 0.26 to 0.55 m for RCP2.6, 0.32 to 0.63 m for RCP4.5, 0.33 to 0.63 m for RCP6.0, and 0.45 to 0.82 m for RCP8.5.

Projections of global mean sea level rise over the 21st century relative to 1986–2005. The assessed likely range is shown as a shaded band.
Future Climate Change (5)

- Cumulative total emissions of CO2 and global mean surface temperature response are approximately linearly related.
- Any given level of warming is associated with a range of cumulative CO2 emissions, and therefore, e.g., higher emissions in earlier decades imply lower emissions later.

Upper amount of cumulative total emissions of CO2 (GtC)

<table>

Impacts of climate change

- In recent decades, changes in climate have caused impacts on natural and human systems on all continents and across the oceans.
- Impacts are due to observed climate change, irrespective of its cause, indicating the sensitivity of natural and human systems to changing climate.
Illustration of the core concepts of the WGII AR5

- Risk of climate-related impacts results from the interaction of climate-related hazards with the vulnerability and exposure of human and natural systems.
- Changes in both the climate system and socioeconomic processes including adaptation and mitigation are drivers of hazards, exposure, and vulnerability.

**Vulnerability:** The propensity or predisposition to be adversely affected. Vulnerability encompasses a variety of concepts and elements including sensitivity or susceptibility to harm and lack of capacity to cope and adapt.

**Exposure:** The presence of people, livelihoods, species or ecosystems, environmental functions, services, and resources, infrastructure, or economic, social, or cultural assets in places and settings that could be adversely affected.
Risk & potential for adaptation

- Adaptation is place- and context-specific, with no single approach for reducing risks appropriate across all settings.

<table>

<th>Climatic drivers</th>
<th>Timeframe</th>
<th>Risk &amp; potential for adaptation</th>
</tr>
</thead>
</table>
| Increased riverine, coastal, and urban flooding leading to widespread damage to infrastructure, livelihoods, and settlements in Asia (medium confidence) [24.4] | • Exposure reduction via structural and non-structural measures, effective land-use planning, and selective relocation  
• Reduction in the vulnerability of lifeline infrastructure and services (e.g., water, energy, waste management, food, biomass, mobility, local ecosystems, telecommunications)  
• Construction of monitoring and early warning systems; Measures to identify exposed areas, assist vulnerable areas and households, and diversify livelihoods  
• Economic diversification                                                   |                  | Present            | Very low          |
|                                                                         |                                                                                               |                  | Near term (2030–2040) | Medium            |
|                                                                         |                                                                                               |                  | Long term 2°C (2080–2100) | Very high         |
| Increased risk of heat-related mortality (high confidence) [24.4]        | • Heat health warning systems  
• Urban planning to reduce heat islands; Improvement of the built environment; Development of sustainable cities  
• New work practices to avoid heat stress among outdoor workers          |                  | Present            | Very low          |
|                                                                         |                                                                                               |                  | Near term (2030–2040) | Medium            |
|                                                                         |                                                                                               |                  | Long term 4°C (2080–2100) | Very high         |
| Increased risk of drought-related water and food shortage causing malnutrition (high confidence) [24.4] | • Disaster preparedness including early-warning systems and local coping strategies  
• Adaptive/integrated water resource management  
• Water infrastructure and reservoir development  
• Diversification of water sources including water re-use  
• More efficient use of water (e.g., improved agricultural practices, irrigation management, and resilient agriculture) |                  | Present            | Very low          |
|                                                                         |                                                                                               |                  | Near term (2030–2040) | Medium            |
|                                                                         |                                                                                               |                  | Long term 3°C (2080–2100) | Very high         |
Total annual anthropogenic greenhouse gas emissions

- Annual GHG emissions grew on average by 2.2 % per year from 2000 to 2010 compared to 1.3 % per year from 1970 to 2000.
- About half of cumulative anthropogenic CO2 emissions between 1750 and 2010 have occurred in the last 40 years.
Characteristics of mitigation pathways (1)

- There are multiple mitigation pathways that are likely to limit warming to below 2 °C relative to preindustrial levels.
- These pathways would require substantial emissions reductions over the next few decades and near zero emission of CO2 and other long-lived GHGs by end of the century.
• At the global level, scenarios reaching about 450 ppm CO2eq are also characterized by more rapid improvements in energy efficiency and a tripling to nearly a quadrupling of the share of zero- and low- carbon energy supply from renewables, nuclear energy and fossil energy with carbon dioxide capture and storage (CCS), or bioenergy with CCS (BECCS) by the year 2050.
Risks from climate change...

- The relationship between risk from climate change, temperature change, cumulative CO2 emissions, and changes in annual GHG emissions by 2050.
Summary of IPCC AR5

- Warming of the climate system is unequivocal.
- The atmosphere and ocean have warmed, the amounts of snow and ice have diminished, sea level has risen, and the concentrations of GHGs have increased.
- Total radiative forcing is positive, and has led to an uptake of energy by the climate system.
- It is extremely likely that human influence has been the dominant cause of the observed warming since the mid-20th century.
- Increase of global mean surface temperatures for 2081–2100 relative to 1986–2005 is projected to 0.3-1.7 °C (RCP2.6), 1.1-2.6 °C (RCP4.5), 1.4-3.1 °C (RCP6.0), 2.6-4.8 °C (RCP8.5).
- Cumulative total emissions of CO2 and global mean surface temperature response are approximately linearly related.
- In recent decades, changes in climate have caused impacts on natural and human systems on all continents and across the oceans.
- There are multiple mitigation pathways that are likely to limit warming to below 2 °C relative to preindustrial levels.
